Heritage Event Management System

Runnable Desktop Project | Python • Tkinter • SQLite • SQL

1. Overview

A desktop application for organizing cultural and heritage events, maintaining visitor records, registering visitors and reviewing attendance summaries.

2. Features

• Add and view events, venues, dates, event types and capacities.
• Add visitors with email validation.
• Register visitors for events and prevent duplicate registrations.
• Check capacity before registration.
• Update registration status to Registered, Attended or Cancelled.
• View reports showing registrations and attendance rates.

3. Technology

Python 3 provides the application logic; Tkinter creates the desktop interface; SQLite stores records locally; SQL demonstrates relational tables, foreign keys, joins and aggregate reporting.

4. How to Run

Extract the ZIP, open Command Prompt in the extracted folder, then run **py app.py**. The local database is created automatically. No additional Python packages or MySQL installation are required.

5. Testing

Try adding an event, adding a visitor, registering that visitor, changing the registration status and checking the Reports tab. Try registering the same visitor for the same event twice; the application should reject the duplicate.

6. Data note

All sample records are fictional and are included for demonstration only. This is an independent portfolio project and not an official IAADB or Ministry of Culture application.
